

IN THE CLAIMS:

Please cancel Claims 14~~4~~3 without prejudice to or disclaimer of the recited subject matter.

Please amend Claims ~~1~~, 4, and 9 and add new Claims 44-70 as follows.

Sub
B1
A1

1. (Currently Amended) A method of detecting a predetermined mark embedded in an image, said mark comprising a predetermined arrangement of a plurality of elements, each element having a predetermined colour characteristic and predetermined shape, the method comprising the steps of:

processing the image to provide an encoded representation of the image at a predetermined resolution;

detecting coordinate positions for substantially each of said elements of the mark embedded in the image, wherein the detection is characterised by applying at least one mask to substantially each pixel of the encoded representation;

determining from said coordinate positions a set of spatial features representing a spatial arrangement of the detected elements; and

comparing the determined set of spatial features to a known set of spatial features to provide a confidence level measure representing a correlation error between the spatial features ~~for a degree of matching between~~ the known set and the determined set of spatial features; and detecting said predetermined mark on the basis of said confidence level measure.

2. (Original) The method of claim 1, wherein the spatial features are features indicating an angular distribution about a predetermined origin for each mark.

3. (Original) The method of claim 2, wherein the features indicating said angular distribution comprise a signature indicating a discrete angular distribution about said origin.

A 2
4. (Currently Amended) Apparatus for detecting a predetermined mark embedded in an image, said mark comprising a predetermined arrangement of a plurality of elements, each element having a predetermined colour characteristic and predetermined shape, the apparatus comprising:

processing means for processing the image to provide an encoded representation of the image at a predetermined resolution;

detecting means for detecting coordinate positions of substantially each of said elements of the mark embedded in the image, wherein the detection is characterised by applying at least one mask to substantially each pixel of the encoded representation;

spatial feature determining means for determining a set of spatial features representing a spatial arrangement of the detected elements; and

comparison means for comparing the determined set of spatial features to a known set of spatial features and outputting a confidence level measure representing a correlation error between the spatial features for a degree of matching between the known set and the determined set of spatial features; and

mark detection means for detecting said predetermined mark on the basis of said confidence level measure.

5. (Original) Apparatus according to claim 4, wherein the spatial feature determining means comprises angular distribution means for determining an angular distribution of said mark elements about a predetermined origin for each mark.

6. (Original) Apparatus according to claim 5, wherein the features indicating said angular distribution comprise a signature indicating a discrete angular distribution about said origin.

7. (Original) Apparatus according to claim 6, wherein the signature comprises a plurality of radial signatures, each said radial signature indicating a discrete angular distribution of each element in a predetermined annular region encircling said origin.

8. (Original) Apparatus according to claim 6, wherein said comparison means compares a signature of the determined spatial feature with a corresponding signature of a known mark

9. (Currently Amended) A computer program product including a computer readable medium having recorded thereon a computer program for detecting a predetermined mark embedded in an image, said mark comprising a predetermined arrangement of a plurality of elements, each element having a predetermined colour characteristic and predetermined shape, the computer program product comprising:

processing means for processing the image to provide an encoded representation of the image at a predetermined resolution;

detecting means for detecting coordinate positions of substantially each of said elements of the mark embedded in the image, wherein the detection is characterised by applying at least one mask to substantially each pixel of the encoded representation;

spatial feature determining means for determining a set of spatial features representing a spatial arrangement of the detected elements; and

A3

comparison means for comparing the determined set of spatial features to a known set of spatial features and outputting a confidence level measure representing a correlation error between the spatial features ~~for a degree of matching between~~ the known set and the determined set of spatial features; and

mark detection means for detecting the predetermined mark on the basis of said confidence level measure.

10. (Original) A computer program product according to claim 9, wherein the spatial feature determining means comprises angular distribution for determining an angular distribution of said mark elements about a predetermined origin for each mark.

11. (Original) A computer program product according to claim 10, wherein the features indicating said angular distribution comprises a signature indicating a discrete angular distribution about said origin.

12. (Original) A computer program product according to claim 11, wherein the signature comprises a plurality of radial signatures, each said radial signature indicating a discrete angular distribution of each element in a predetermined annular region encircling said origin.

13. (Original) A computer program product according to claim 11, wherein said comparison means compares a signature of the determined spatial feature with a corresponding signature of a known mark.

14-43. (Cancelled)

44. (New) Apparatus for detecting a predetermined mark embedded in an image, said mark comprising a predetermined arrangement of a plurality of elements, each element having a predetermined colour characteristic and predetermined shape, the apparatus comprising:

processing means for processing the image to provide an encoded representation of the image at a predetermined resolution;

detecting means for detecting coordinate positions of substantially each of said elements of the mark embedded in the image, wherein the detection is characterised by applying at least one mask to substantially each pixel of the encoded representation;

spatial feature determining means for determining a plurality of radial signatures, each said radial signature indicating a discrete angular distribution of each element in about a predetermined origin;

comparison means for comparing the determined set of spatial features to a known set of spatial features and outputting a confidence level measure representing a correlation error between the spatial features of the known set and the determined set of spatial features; and

mark detecting means for detecting said predetermined mark on the basis of said confidence level measure.

45. (New) A computer program product including a computer readable medium having recorded thereon a computer program for detecting a predetermined mark embedded in an image, said mark comprising a predetermined arrangement of a plurality of elements, each element having a predetermined colour characteristic and predetermined shape, the computer program product comprising:

processing means for processing the image to provide an encoded representation of the image at a predetermined resolution;

detecting means for detecting coordinate positions of substantially each of said elements of the mark embedded in the image, wherein the detection is characterised by applying at least one mask to substantially each pixel of the encoded representation;

spatial feature determining means for determining a plurality of radial signatures, each said radial signature indicating a discrete angular distribution of each element in about a predetermined origin;

comparison means for comparing the determined set of spatial features to a known set of spatial features and outputting a confidence level measure representing a correlation error between the spatial features of the known set and the determined set of spatial features; and

mark detection means for detecting said predetermined mark on the basis of said confidence level.

46. (New) Apparatus according to claim 4, wherein said image data comprising a plurality of pixels, each said pixel being represented using multiple colour channels, said apparatus comprising:

pixel buffer pipe means, having an input means for receiving said image data in a predetermined order and for detecting transitions between foreground and background pixels;

a pixel selection means for subsampling said image data in a first direction in accordance with an intensity of one said colour channel of the image data to provide a first desired resolution in said first direction;

foreground density checking means for receiving said one colour channel and outputting;

- a) if an intensity value of one said colour channel is below a first predetermined threshold value, a first token;

- Sub
251
- b) if the intensity value of said one colour channel is above a second predetermined threshold value, a second token; or
 - c) if the intensity value of said one colour channel is intermediate the first and second threshold values:
 - ca) the first token when a transition is detected at the pixel buffer pipe means;
 - and
 - cb) the second token when a transition is not detected at the pixel buffer pipe means;

44
encoding means for receiving at least one other of said colour channels and selectively grouping each pixel represented in said at least one other colour channel into one group of a plurality foreground colour groups if the output of said foreground density checking means is the first token and grouping into a background colour group if the output of said foreground density checking means is the second token, said encoding means outputting for each pixel a representation of the corresponding group; and

output buffer means for receiving said representation and providing a subsampling in a second direction of the image data to achieve a second desired resolution in said second direction.

47. (New) Apparatus according to claim 46, wherein further comprising subsample control means for further subsampling in said second direction according to a magnification value and an input resolution value.

48. (New) Apparatus according to claim 47, wherein said transition is determined by the pixel buffer pipe means using lead pixels and lag pixels.

49. (New) Apparatus according to claim 48, wherein said predetermined order comprises a raster scan order.

Sub
B.1
50. (New) Apparatus according to claim 49, wherein said transition is a transition from background pixel to foreground pixel.

51. (New) Apparatus according claim 50, wherein said first and second desired resolutions are substantially the same resolution.

44
52. (New) A method according to claim 1, wherein said image data comprises a plurality of pixels, each said pixel being represented using multiple colour channels, the method comprising the steps of;

inputting pixels in a predetermined order and detecting transitions between foreground and background pixels;

subsampling in a first direction of the image data in accordance with an intensity of one said colour channel of the image data to provide a first desired resolution in said first direction;

examining said one colour channel and outputting:

- a) if an intensity value of said one colour channel is below a first predetermined threshold value, a first token;
- b) if the intensity value of said one colour channel is above a second predetermined threshold value, a second token; or
- c) if the intensity value is intermediate the first and second threshold values:
 - ca) the first token when a transition is detected upon inputting said pixels; and

cb) the second token when a transition is not detected upon inputting said pixels;

Sub 15
encoding each said pixel by selectively grouping each said pixel represented in at least one other of said colour channels into one group of a plurality foreground colour groups if said examining step outputs a first token and grouping into a background colour group if said examining step outputs a second token, and outputting for each pixel a representation of the corresponding group; and

A4
subsampling in a second direction of the image data to achieve a second desired resolution in said second direction.

53. (New) A method according to claim 52, wherein said transition is determined using lead pixels and lag pixels.

54. (New) A method according to claim 53, wherein said foreground pixel is a pixel having colour value belonging to a predetermined set colour values and the background pixel is a pixel which is not a foreground pixel.

55. (New) A method according to claim 54, wherein said predetermined order is raster scan order.

56. (New) A method according to claim 55, wherein said transition is a transition from background pixel to foreground pixel.

57. (New) A method according to claim 56, wherein said transition is a transition from background pixel to foreground pixel.

58. (New) A computer program product according to claim 9, wherein said image data comprises a plurality of pixels, each pixel being represented using multiple colour channels, the computer program product comprising;

pixel buffer pipe means, having an input means for receiving said image data in a predetermined order and for detecting transitions between foreground and background pixels;

pixel selection means for subsampling said image data in a first direction in accordance with an intensity of one said colour channel of the image data to provide a first desired resolution in said first direction;

foreground density examining means for receiving said one colour channel and outputting:

- a) if an intensity value of said one colour channel is below a first predetermined threshold value, a first token;
- b) if the intensity value of said one colour channel is above a second predetermined threshold value, a second token; or
- c) if the intensity value of said one colour channel is intermediate the first and second threshold values;
 - ca) the first token when a transition is detected at the pixel buffer pipe means; and
 - cb) the second token when a transition is not detected at the pixel buffer pipe means;

Sub
B1
encoding means for receiving at least one other of said colour channels and selectively grouping each pixel represented in said at least one other colour channel into one group of a plurality foreground colour groups if the output of said foreground density examining means is a first token and grouping into a background colour group if the output of said foreground density checking means is a second token, said encoding means outputting for each pixel a representation of the corresponding group; and

A4
output buffer means for receiving said representation and providing a subsampling in a second direction of the image data to achieve a second desired resolution in said second direction.

59. (New) A computer program product according to claim 58, wherein said transition is determined by the pixel buffer pipe means using lead pixels and lag pixels.

60. (New) A computer program product according to claim 59, wherein said first and second desired resolutions are substantially the same resolution.

61. (New) Apparatus according to claim 4, wherein said image comprising a plurality of pixels, each said pixel being encoded either as a foreground or background pixel, said predetermined pattern being intended to substantially match a predetermined reference pattern, the reference pattern being represented by a mask arranged as a two dimensional array of cells, the cells having indicated thereon whether the reference pattern comprises foreground pixels, background pixels or neither, said apparatus comprising:

input means for receiving a plurality of one dimensional arrays of pixel values of said image, wherein each said array being received sequentially;

Sub 21
foreground adder means for generating a plurality of partial sums of said foreground pixels, for each array of pixel values, intended to match with the reference pattern of the mask, wherein each partial sum of said foreground pixels substantially corresponds to an application of a slice of said mask;

background adder means for generating a plurality of partial sums of said background pixels, for each array of pixel values, intended to match with the reference pattern of the mask, wherein each partial sum of said background pixels substantially corresponds to the application to the application of said slice;

44
a foreground accumulator network for providing a total foreground count value of said plurality of partial sums for a predetermined number of input arrays of pixel values;

a background accumulator network for providing a total background count value of said plurality of partial sums for the predetermined number of input arrays of pixel values;

thresholding means for thresholding the total foreground count value and the total background count value against first and second predetermined threshold values respectively and outputting a value reflecting each threshold comparison; and

determining means for determining from each output value whether or not the predetermined pattern is detected.

62. (New) Apparatus according to claim 61, wherein said image comprises a plurality of scan lines, each said scan line having a plurality of pixel values and said one dimensional array comprises a predetermined number of pixel values of corresponding locations on a plurality of adjacent scan lines.

63 (New) Apparatus according to claim 61, wherein said apparatus forms a pipeline circuit for pipelining the sequences of one dimensional arrays.

64. (New) A method according to claim 1, wherein said image comprises a plurality of pixels, each said pixel being encoded either as foreground or background pixel, said predetermined pattern substantially matching a predetermined reference pattern, the reference pattern being representable by a mask arranged as a two dimensional array of cells, each cell having indicated thereon whether the cell is a foreground pixel, background pixel or neither, the method comprising the steps of:

providing a plurality of one dimensional arrays of pixel values of said image, wherein each array is provided sequence;

generating a plurality of partial sums of foreground pixels for a current one dimensional array of pixel values which match with foreground cells of the reference pattern of a slice of the mask;

generating a plurality of partial sums of background pixels for the current one dimensional array of pixel values which match with background cells of the reference pattern of said slice of the mask;

accumulating the partial sums of foreground pixels for a predetermined number of input one dimensional arrays of pixel values to provide a total foreground count value;

accumulating the partial sums of background pixels for a predetermined number of input one dimensional arrays of pixel values to provide a total background count value;

thresholding the total foreground count value and the total background count value against a first and second predetermined threshold value respectively and outputting a value reflecting each threshold comparison; and

determining from each output value whether or not the predetermined pattern is detected.

65. (New) A method according to claim 64, wherein said foreground pixels are pixels having one colour selected from a first set of colour values and said background pixels are pixels having one colour selected from a second predetermined set of colour values.

66. (New) A method according to claim 65, wherein each cell of the slice of the mask corresponds with a pixel value of the one dimensional array.

67. (New) A method according to claim 1, wherein said image comprises a plurality of pixels, each said pixel being either on or off, said predetermined pattern substantially matching a predetermined reference pattern, the reference pattern being representable by a mask arranged as a two dimensional array of cells, each cell having indicated thereon whether the cell is on or off, the method comprising the steps of:

providing a plurality of one dimensional arrays of pixel values of said image, wherein each array is provided sequence;

generating a plurality of partial sums of on pixel values for a current one dimensional array of pixel values which match with an on cell of the reference pattern of a slice of the mask;

accumulating the partial sums for a predetermined number of input one dimensional arrays of pixel values; and

thresholding the accumulated partial sums against a predetermined threshold value and determining whether or not the predetermined pattern is detected based on the threshold comparison.

68. (New) A computer program product according to claim 9, wherein said image comprises a plurality of pixels, each said pixel being encoded either as a foreground or background pixel, said predetermined pattern substantially matching a predetermined reference pattern, the reference pattern being represented by a mask arranged as two dimensional array of cells, the cells having indicated thereon whether the reference pattern is foreground pixel, background pixel or neither, the computer program product comprising:

input means for receiving a plurality of one dimensional arrays of pixel values of said image, wherein each array is received sequentially;

foreground adder means for generating a plurality of partial sums of foreground pixels, for each array of pixel values, which match with the reference pattern of the mask, wherein each partial sum substantially corresponds to an application of a slice of said mask;

background adder means for generating a plurality of partial sums of background pixels, for each array of pixel values, which match with the reference pattern of the mask, wherein each partial sum of background pixels substantially corresponds to the application of said slice;

a foreground accumulator network for providing a total foreground count value of said plurality of partial sums for a predetermined number of input arrays of pixel values;

a background accumulator network for providing a total background count value of said plurality of partial sums for the predetermined number of input arrays of pixel values;

thresholding means for thresholding the total foreground count value and the total background count value against a first and second predetermined threshold value respectively and outputting a value reflecting each threshold comparison; and

determining means for determining from each output value whether or not the predetermined pattern is detected.

69. (New) A computer program product according to claim 68, wherein said image comprise a plurality of scan lines, each scan line having a plurality of pixel values and said one dimensional array comprises a predetermined number of pixel values of corresponding locations on a plurality of adjacent scan lines.

70. (New) A computer program product according to claim 69, wherein said foreground pixels are pixels having one colour selected from a first set of colour values and said background pixels are pixels having one colour selected from a second predetermined set of colour values.
